Forbidden Lines in ns^2np^k Ground Configurations and $nsnp$ Excited Configurations of Beryllium through Molybdenum Atoms and Ions

Victor Kaufman and Jack Sugar

National Bureau of Standards, Gaithersburg, MD 20899

Observed and predicted wavelengths of magnetic dipole lines arising within ground configurations of the type ns^2np^k ($n=2$ and 3, $k=1$ to 5) are compiled. For $n=2$ the compilation includes the elements B through Kr, and for $k=5$ it extends to Mo. For $n=3$ Al through Mo are included. In addition the $2s2p$ excited configuration of the Be I isoelectronic sequence for Be through Kr and $3s3p$ of the Mg sequence for Mg through Mo are included. For each line we give a calculated value for the transition probability obtained mainly from the Dirac-Fock method or from the use of scaled radial integrals. The calculated wavelengths are obtained from known energy levels or from levels derived from scaled radial integrals. A small group of electric quadrupole lines seen in astronomical sources are included. The list contains 1660 predicted wavelengths in the range 100 Å to 25.9 mm and 406 observed wavelengths in the range 325 Å to 609 μm.

Key words: astronomy; magnetic-dipole lines; spectra; tokamak; transition probabilities; wavelengths.

List of Tables

1. Introduction

Forbidden lines have long been used in the analysis of astrophysical plasmas (solar, stellar, nebular, etc.). In the infrared they are among the strongest stellar lines, and many of those of the light atoms have been measured. Spectra of the solar corona and solar flares are rich in magnetic dipole lines (M1) in the visible and ultraviolet for the elements nitrogen through nickel. In recent years these lines have achieved new importance for diagnostics of low-density, magnetically-confined, high-temperature laboratory plasmas generated in tokamaks. This research has extended the range of elements of interest to heavier atoms that may be injected into the plasma to measure ion temperatures in the range of 0.5 to 20 keV by Doppler broadening and to observe plasma dynamics such as plasma rotation and transport of impurities.

On the basis of recent advances in the determination of energy level structures of highly ionized atoms of the iron period, one may predict the wavelengths of M1 lines with high accuracy for this range of elements. From a study of the behavior of the radial energy integrals fitted to these levels, and from numerous M1 lines identified for ions of copper to molybdenum, it became possible to extend the predictions to ions through molybdenum. We have compiled the observed and predicted wavelengths of magnetic dipole lines arising within ground configurations of the type ns^2np^k ($n=2$ and 3, $k=1$ to 5). For $n=2$, we include the elements B through Kr, and for $k=5$ the tables extend to Mo. For $n=3$, Al through Mo are included. In addition, the $2s2p$ excited configuration of the Be I isoelectronic sequence for Be through Kr and $3s3p$ of the Mg I sequence for Mg through Mo are included.

It will probably be difficult to observe the *nsnp* ($^3P_{0,1,2}-{}^1P_1$) transitions in the Be I and Mg I sequences because the very large electric-dipole transition probability of the $ns^2\,{}^1S_0-nsnp\,{}^1P_1$ resonant transition will tend to rapidly deplete the $nsnp\,{}^1P_1$ level. Similarly, but to a lesser extent, the $^3P_0-{}^3P_1$ transition can be expected to be weak because of the $ns^2\,{}^1S_0-nsnp\,{}^3P_1$ transition. However, we have included these magnetic-dipole transitions for the sake of completeness.

All measured lines that we consider correctly identified are included. Some are only tentatively classified by the authors, but appear to be reasonable on the basis of predictions along isoelectronic sequences. Some are omitted because they are far from satisfying this criterion.

We have also included a selected group of electric quadrupole lines (E2) that are frequently observed in ns^2np^2 and ns^2np^4 configurations; these are the $^1D_2-{}^1S_0$ transitions.

Calculations of line strengths and transition probabilities have been made for all of these lines by both relativistic and non-relativistic methods. We have given preference to the relativistic results. Calculations by both methods for the $n=3$ shell differ on the average by only 5% (see Sec. 6, Ref. 1).

2. Predicted Wavelengths

For Be through Ni, predicted values for the wavelengths of the M1 and E2 lines were obtained from the known energy levels by the Ritz principal of deriving wavelengths from energy differences. Their uncertainties are derived from the reported level uncertainties. The source of data for each of these atoms and ions is given in Sec. 7 below.

From Cu through Mo predictions of wavelengths of M1 lines within the $3s^23p^k$ configurations by Sugar and Kaufman[1] are quoted. These are preferred to *ab initio* calculations because they are semi-empirically derived

by fitting radial energy integrals to the known levels beginning with potassium, and have been found to give more accurate wavelength predictions. The uncertainty estimates are derived as prescribed in that paper. Contributions to the uncertainty by each integral in the calculation was estimated, and the combined effect was given as a monotonically increasing function of atomic number. These estimates appear to be high by a factor of two, as indicated by many subsequently identified lines.

We predicted the lines of the $3s3p$ configurations for inclusion here. The radial integrals $G^1(sp)$ and ζ_p were fit to known levels from potassium to molybdenum. These parameters were then interpolated for ions for which the levels are not known, and predictions were made by diagonalizing the energy matrices. Measured emission lines of copper in this sequence from Sugar and Kaufman[2] were combined with the M1 transition $3s3p\ ^3P_2-{}^3P_1$ from Denne *et al.*[3] to establish the levels of this ion. Denne *et al.* measured this same transition for Ge, Se, Zr, and Mo. The intersystem lines $3s^2\ ^1S_0-3s3p\ ^3P_1$ were observed by Finkenthal *et al.*[4] for Ge, Se, Zr, and Mo. Values for the $3s^2\ ^1S_0-3s3p\ ^1P_1$ lines were provided by Fawcett and Hayes[5] for Zn to Se and from Reader[6] for Sr to Mo.

Edlén has made a comparison of the known levels of the $n=2$ shell (Li to F sequences) with the relativistic Dirac-Fock *ab initio* calculations available in the literature, and has derived analytical expressions for the differences. By this means he has predicted level values through Kr. We used his results to obtain predicted wavelengths from Cu to Kr for the beryllium-to-oxygen isoelectronic sequences[7-10] and from Cu to Mo for the fluorine isoelectronic sequence.[7]

We include a total of 1660 predicted wavelengths.

3. Observed Wavelengths

With a few exceptions the M1 and E2 lines of carbon through argon have been observed only from astronomical sources, including gaseous nebulae, stars, and the solar corona. These sources have also provided considerable iron-period data. The most common laboratory source generating copious forbidden lines is the tokamak, which contains a magnetically-confined, high-temperature plasma with an ion density similar to that of the solar corona. By injecting any impurity element, magnetic dipole lines of that element may be seen in stages of ionization determined by the plasma temperature. All of the scandium and titanium data, most of the chromium and nickel data, and all from copper to molybdenum are from tokamak observations.

We have included a small group of E2 lines comprising the $^1D_2-{}^1S_0$ transition of the ns^2np^2 and ns^2np^4 configurations ($n=2$, 3) because of their prominence in nebular sources.

The sources of observed data that we have credited are not necessarily the original discoverers of the lines, but are those providing the best measurements. In some cases, such as for spectra of the solar corona, the authors have given the line identifications for wavelengths observed by others. References for the observed wavelengths are given in Sec. 8, each preceded by a symbol that is used to identify them in the tables. We include 406 observed wavelengths.

4. Predicted Transition Probabilities

In most cases multiconfiguration Dirac-Fock calculations of line strengths are available. These calculations do not generally converge for neutral and singly ionized atoms, but non-relativistic calculations have been made in every such case. Line strengths for the magnetic-dipole lines of Be I, B I, B II, C I, C II, N I, N II, O I, O II and F II were taken from Wiese *et al.*[11] Those for Si I and P I were taken from Wiese *et al.*[12] Line strengths for the magnetic-dipole lines of the isoelectronic sequences of B I, C I, N I and F I were taken, except as noted above, from Cheng *et al.*[13] Those for the Al I, Si I, and P I sequences were taken, except as noted above, from Huang.[14-16] Those for the Cl I sequence, with a few exceptions, are from Huang *et al.*[17] For Cl-like Ga, Ge, As, Y and Zr the line strengths were interpolated from values of neighboring ions. The relativistic calculations are not available for the Be, Mg, and S isoelectronic sequences. The transition probabilities for all magnetic-dipole lines of the Be-like, Mg-like, and S-like ions were calculated in the manner described in Sugar and Kaufman.[1] These are non-relativistic calculations in intermediate coupling. They agree within a few percent with relativistic calculations in the $n=3$ sequences for which both are available.

Line strengths for the electric-quadrupole lines of $2s^22p^k\ (^1D_2-{}^1S_0)$ [$k=2$] of C I and N II and [$k=4$] of O I and F II are from Wiese *et al.*[11] Those for the remainder of the carbon sequence, O III through Ni XXIII, and for the remainder of the oxygen sequence, Ne III through Ni XXI, are from Cheng *et al.*[13] The transition probabilities for these lines in the sulfur sequence, $3s^23p^4$, for S I through Ni XIII, are from Mendoza and Zeippen.[18] Those from Cu XIV through Mo XXVII are from Biemont and Hansen.[19] The one for Si I, $3s^23p^2$, is from Mendoza and Zeippen.[20] For the remainder of this sequence, P II through Mo XXIX, we used the line strengths given by Huang.[15]

Relations between transition probabilities $A(s^{-1})$ and line strengths S are given explicitly as

$$A = \frac{2.697 \times 10^{13}}{\lambda^3 g} S(\mathrm{M1}),$$

$$A = \frac{1.680 \times 10^{18}}{\lambda^5 g} S(\mathrm{E2}),$$

where λ is the transition wavelength in Å and g is the $2J+1$ degeneracy of the upper level. S(M1) in Bohr magneton units (μ_B) and S(E2) in atomic units (ea_0^2) are the magnetic-dipole and electric-quadrupole line strengths, respectively.

The magnetic-dipole transition rate in almost all cases is a few orders of magnitude greater than the electric-quadrupole transition rate. We have added the E2 rate to the M1 rate in those cases for which the former is greater than 1 % of the latter. This is true only for some of the N I ($2p^3$) and P I ($3p^3$) sequence transitions. An asterisk following the transition rate in the tables shows where this occurs.

5. Data Table Information

The tables contain the predicted and observed wavelengths and predicted transition probabilities for magnetic-dipole transitions within ns^2np^k ($k=1-5$) and $nsnp$ configurations; $n=2$ for beryllium through sodium, $n=2$, 3 for magnesium through krypton, and $n=3$ for rubidium through molybdenum. The F-sequence is given through molybdenum. The electric quadrupole transition $^1D_2-{}^1S_0$ for $k=2$, 4 is included because it is frequently observed. The data are presented in two formats. In Tables 1–39 the lines are segregated according to element and within each element are listed in order of increasing wavelength. In Table 40 all lines are merged and sorted by wavelength. The columns from left to right in order of appearance contain the following information:

Column No.	Description
1	Wavelengths (observed and predicted) in Å below 20 000 Å, in micrometers (μm) between 2 and 1000 μm, and in millimeters (mm) between 1 and 26 mm. Wavelengths given without units are in Å. Wavelengths in vacuum are given below 2000 Å, in air between 2000 Å and 5 μm, and in vacuum above 5 μm. Each wavelength is followed by its uncertainty in parentheses. Tentative identifications are preceded by "T".
2	Transition probabilities (A) are written as a factor times 10 to a power. The power of ten follows the decimal factor. For example, 2.20 +4 means 2.20×10^4. An asterisk following the transition probability indicates that the E2 rate for the transition is greater than 1 % of the M1 rate and has been added to that value.
3	Spectrum.
4	Electronic configuration.
5	Line classification. Lower level is given first.
6	Ionization energy in thousands of electron volts (keV).[21–23]
7	References for observed wavelengths. Definitions of symbols are given in Sec. 8, "References for Observed Wavelengths."

[a]This is a wavelength in vacuum.

[b]Alternate wavelengths for these transitions were given by reference BGBR. They are 4424.1(2) and 5593.9(6) Å for Se XXI and Se XIX, respectively.
